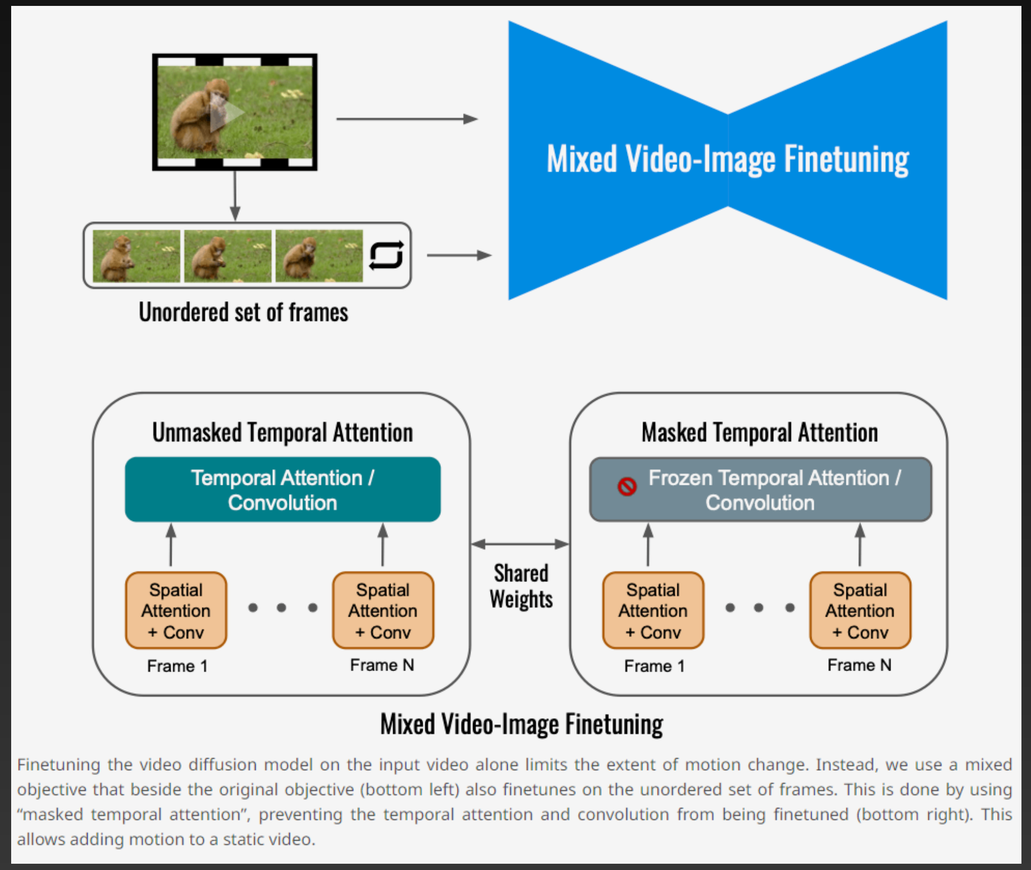
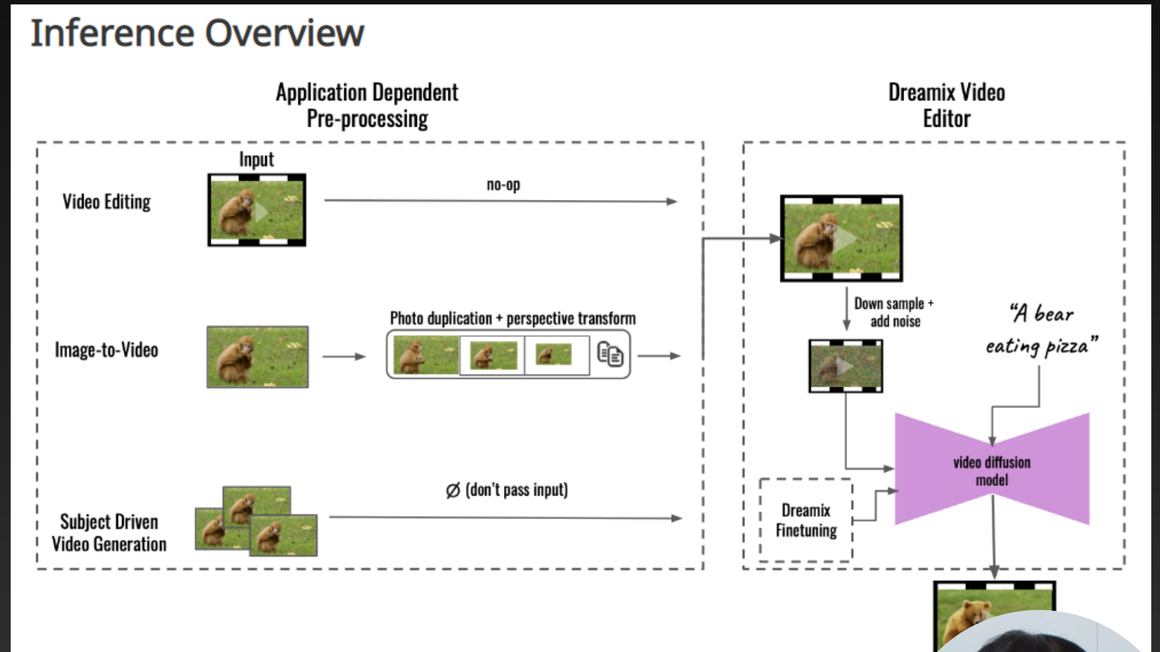
- Dreamix: Video Diffusion Models are General Video Editors



Mixed Video-Image Finetuning

Finetuning the video diffusion model on the input video alone limits the extent of motion change. Instead, we use a mixed objective that beside the original objective (bottom left) also finetunes on the unordered set of frames. This is done by using "masked temporal attention", preventing the temporal attention and convolution from being finetuned (bottom right). This allows adding motion to a static video.



Our method supports multiple applications by application dependent pre-processing (left), convertin
uniform video format. For image-to-video, the input image is duplicated and transformed using pe
synthesizing a coarse video with some camera motion. For subject driven video generation, the in
alone take care of the fidelity. This coarse video is then edited using our general ``Dreamix Video Edi
the video by downsampling followed by adding noise. We then apply the finetuned text-guided vid
upscales the video to the final spatio-temporal resolution

- Accelerating Large Language Model Decoding with Speculative Sampling
  - 초거대 언어모델에서 디코딩 속도 올리기 위해 제안하는 새로운 sampling 기법 (from DeepMind)
  - 순서는 아래와 같습니다.
    - Generating a short draft of length K. This can be attained with either a parallel model (Stern et al., 2018) or by calling a faster, auto-regressive model K times. We shall refer to this model as the draft model, and focus on the case where it is auto-regressive.
    - Scoring the draft using the larger, more powerful model from we wish to sample from. We shall refer to this model as the target model.
    - Using a modified rejection sampling scheme, accept a subset of the K draft tokens from left to right, recovering the distribution of the target model in the process.

- Accelerating Large Language Model Decoding with Speculative Sampling
  - 그런데 사실 Google의 Fast Inference from Transformers via Speculative Decoding 랑 거의 같음. LAMDA vs. Chinchilla

Table 1 | **Chinchilla performance and speed on XSum and HumanEval with naive and speculative sampling at batch size 1 and** $K = 4$. XSum was executed with nucleus parameter $p = 0.8$, and HumanEval with $p = 0.95$ and temperature 0.8.

Sampling Method	Benchmark	Result	Mean Token Time	Speed Up
ArS (Nucleus)	XSum (ROUGE-2)	0.112	14.1ms/Token	1×
SpS (Nucleus)		0.114	7.52ms/Token	1.92×
ArS (Greedy)	XSum (ROUGE-2)	0.157	14.1ms/Token	1×
SpS (Greedy)		0.156	7.00ms/Token	2.01×
ArS (Nucleus)	HumanEval (100 Shot)	45.1%	14.1ms/Token	1×
SpS (Nucleus)		47.0%	5.73ms/Token	2.46×

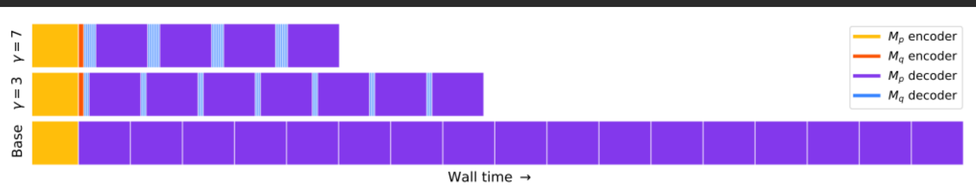

Figure 5. A simplified trace diagram for a full encoder-decoder Transformer stack. In this case we have enough computational power so that the calls to M_p all take about the same time. The top row shows decoding with our method with $\gamma = 7$ so each of the calls to M_p (the purple blocks) is preceded by 7 calls to M_q (the blue blocks). The yellow block on the left is the call to the encoder for M_p and the orange block is the call to the encoder for M_q. Likewise the middle row shows our method with $gamma = 3$, and the bottom row shows standard decoding.

- SingSong: Generating musical accompaniments from singing
  - Keyword : vocal accompaniment
  - Sample URL : https://storage.googleapis.com/sing-song/index.html
  - vocal (노래)를 입력으로 주면 accompaniment (반주)를 만들어주는 모델
  - pre-trained w2v-BERT와 SoundStream을 이용하여 semantic 정보와 acoustic feature를 추출
  - 입력 vocal에서 semantic 정보를 추출하고 타겟 반주는 semantic 정보와 acoustic fature를 이용하는게 best
  - source separation 모델로 뽑은 vocal에 대해 성능 저하 -> 모든 vocal에 노이즈를 추가하여 학습 -> 일반화 성능 up!

ArXiv

- SingSong: Generating musical accompaniments from singing
  - 관련 있는 연구 : Pop2Piano : Pop Audio-based Piano Cover Generation

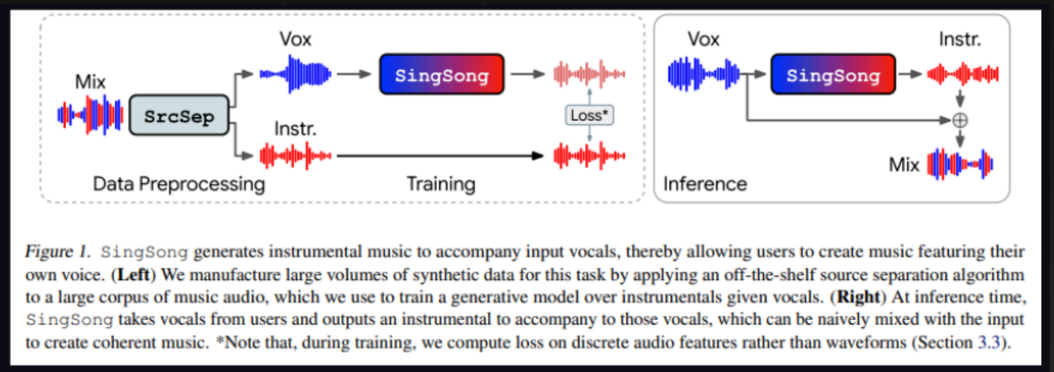

Figure 1. SingSong generates instrumental music to accompany input vocals, thereby allowing users to create music featuring their own voice. (**Left**) We manufacture large volumes of synthetic data for this task by applying an off-the-shelf source separation algorithm to a large corpus of music audio, which we use to train a generative model over instrumentals given vocals. (**Right**) At inference time, SingSong takes vocals from users and outputs an instrumental to accompany to those vocals, which can be naively mixed with the input to create coherent music. *Note that, during training, we compute loss on discrete audio features rather than waveforms (Section 3.3).

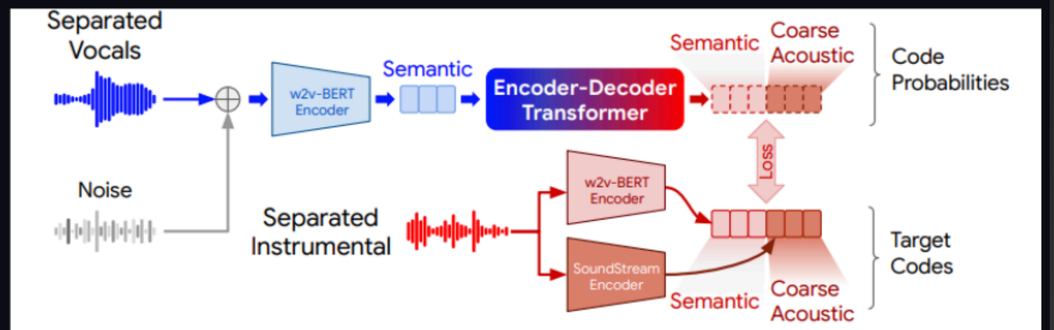

Figure 2. We adapt AudioLM (Borsos et al., 2022) to be suitable for training conditional "audio-to-audio" generative models of instrumentals given vocals. During training, we use source-separated vocals and instrumentals as inputs and targets respectively. We add white noise to the input to conceal residual artifacts of the instrumental present in the source-separated vocals. For the targets, we reuse the discrete featurization scheme from AudioLM, extracting *semantic* codes from a pre-trained w2v-BERT model (Chung et al., 2021) and *coarse acoustic* codes from a pre-trained SoundStream codec (Zeghidour et al., 2021). We experiment with several featurizations of the input—our best model uses only semantic codes of the noisy vocals. We train T5 (Raffel et al., 2020), an encoder-decoder Transformer (Vaswani et al., 2017), to predict target codes given input codes. During inference (not shown), we use this model to generate coarse acoustic codes, then use a separately-trained model to generate fine codes given coarse, and finally decode both with SoundStream.

ArXiv

- SingSong: Generating musical accompaniments from singing
  - 결과는 Frechet Audio Distance (FAD)를 이용하여 비교하거나 선호도 조사를 함
  - 학습 데이터는 46k 시간의 음악, 평가는 MUSDB 18 dataset (10시간의 vocal, instrumental "stems")

	Method	FAD_i	FAD_s	Δ
Clean	SA-SA	3.01	1.61	1.39
	S-SA	2.31	**1.14**	1.17
Noisy	SA-SA	2.01	1.64	0.37
	A-A	3.41	3.30	**0.11**
	SA-A	2.81	1.87	0.95
	A-SA	2.01	1.65	0.36
	S-SA	**1.36**	1.17	0.19
	S-SA-XL	**1.28**	**0.96**	0.32

Table 1. Quantitative evaluation for our experiments. FAD is the Fréchet Audio Distance on MUSDB18-test between ground truth mixes and mixes of ground truth vocals and instrumentals generated by models using either isolated vocals (FAD_i) or source-separated vocals (FAD_s) as inputs. Since FAD_i corresponds better to the anticipated usage, and FAD_s is closer to how the model is trained, a generalization gap (Δ) exists between the two. Adding noise to the input vocals (`Noisy`), removing the vocal acoustic codes (`S-SA`), and increasing model size (`XL`) all help to improve generation to isolated vocal inputs (FAD_i). Full details of featurizations can be found in Section 4.5. For all experiments, FAD on MUSDB18-dev is used as an early stopping metric.

- InstructTTS: Modelling Expressive TTS in Discrete Latent Space with Natural Language Prompt
  - Keyword : TTS, prompt, diffusion
  - Sample URL : http://dongchaoyang.top/InstructTTS/
  - content text와 style prompt를 입력으로 expressive한 TTS를 만들어주는 모델
  - 기존의 expressive TTS 방법론에서의 one-to-many 문제를 prompt 기반의 style로 해결
  - PromptTTS와 다른 점은 PromptTTS는 5개의 스타일(성별, 피치, 속도, 크기, 감정)만 하지만 InstructTTS는 무형식!
  - Style encoder로부터 prompt로 부터 semantic 정보를 추출하고 VQ를 이용하여 mel 대신 코드를 이용

ArXiv

- InstructTTS: Modelling Expressive TTS in Discrete Latent Space with Natural Language Style Prompt
  - 관련 있는 연구 : PromptTTS: Controllable Text-to-Speech with Text Descriptions

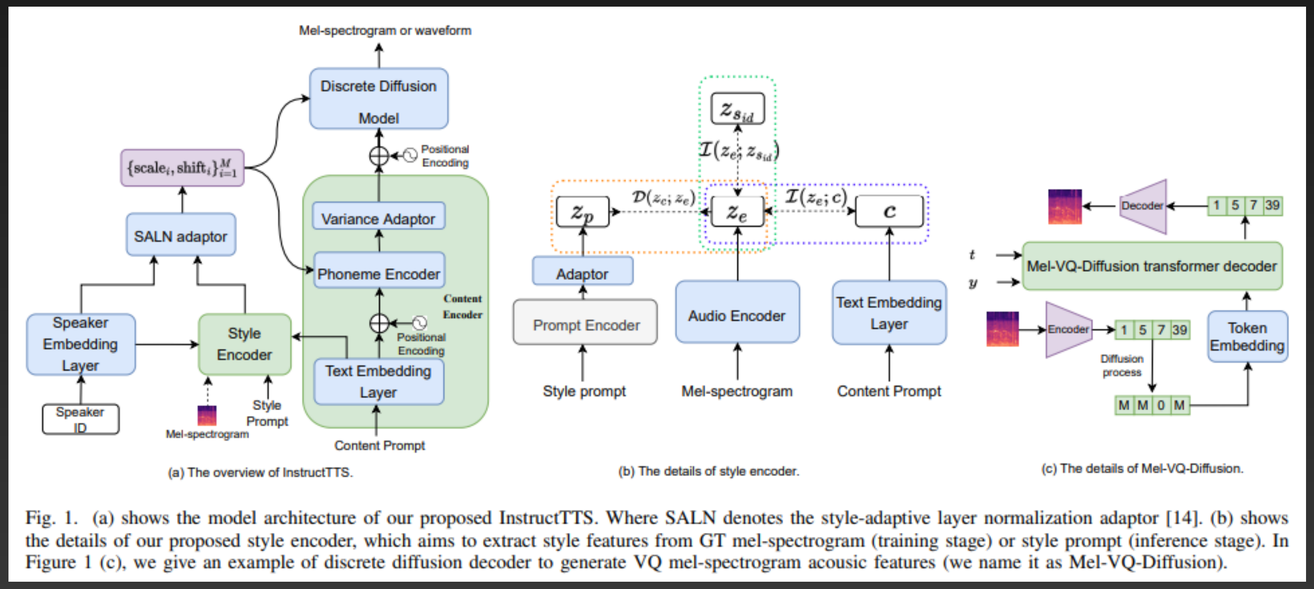

Fig. 1. (a) shows the model architecture of our proposed InstructTTS. Where SALN denotes the style-adaptive layer normalization adaptor [14]. (b) shows the details of our proposed style encoder, which aims to extract style features from GT mel-spectrogram (training stage) or style prompt (inference stage). In Figure 1 (c), we give an example of discrete diffusion decoder to generate VQ mel-spectrogram acousic features (we name it as Mel-VQ-Diffusion).

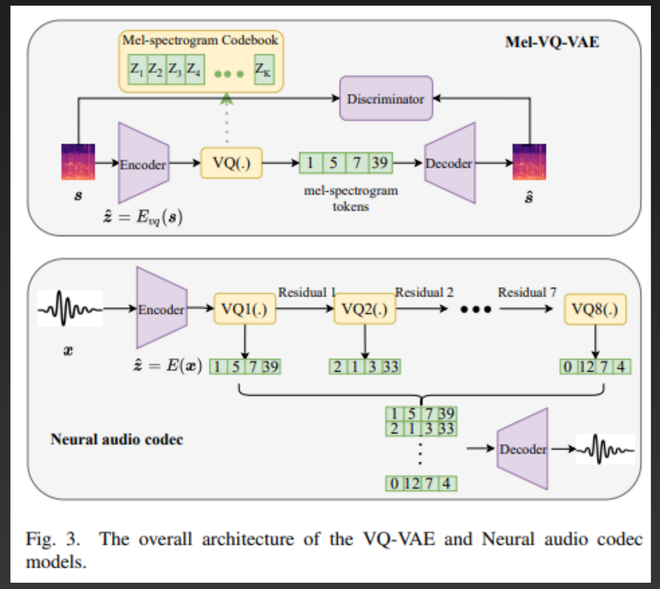

Fig. 3. The overall architecture of the VQ-VAE and Neural audio codec models.
